National Cheng Kung University

Inheritance

- ❑ The sharing of attributes and operations among classes based on a hierarchical relationship
 - It allows code to be *reused*, without having to copy it into the definitions of the derived classes

- ❑ Each subclass inherits all of the properties of its superclass and adds its own unique properties (called extension)

- ❑ **Is-a** relationship

Introduction to Inheritance

- ❑ The original class is called the *base class*
- ❑ The new class is called a *derived class*
 - A derived class automatically has all the instance variables and methods that the base class has, and it can have additional methods and/or instance variables as well

Examples of Derived Classes

- ❑ Within Java, a class called **Employee** can be defined that includes all employees
- ❑ This class can then be used to define classes for hourly employees and salaried employees
 - In turn, the **HourlyEmployee** class can be used to define a **PartTimeHourlyEmployee** class, and so forth

```
public class HourlyEmployee extends Employee
```

A Class Hierarchy

Display 7.1 A Class Hierarchy

Derived Class (Subclass)

- ❑ Members of a class that are declared **private** are not inherited by subclasses of that class.
- ❑ Only members of a class that are declared **protected** or **public** are inherited by subclasses declared in a package other than the one in which the class is declared.

Lab

```
import java.util.Date;

public class Employee {

    protected String name;
    protected Date hireDate;

    public Employee(){}

    public Employee(String theName, Date theDate){
        name = theName;
        hireDate = theDate;
    }
    public Date getHireDate(){
        return hireDate;
    }

    public String getName(){
        return name;
    }
}
```

Lab

```
import java.util.Date;

public class HourlyEmployee extends Employee{
    private double wageRate;

    public HourlyEmployee(String theName, Date theDate, double rate){
        name = theName;
        hireDate = theDate;
        wageRate = rate;
    }
}
```

Lab

```
import java.util.Date;

public class Company {

    public static void main(String[] args){

        HourlyEmployee hourlyEmployee = new HourlyEmployee("Josephine",
            new Date(114,0,1), 100);

        System.out.println(hourlyEmployee.getName());

    }
}
```

Parent and Child Classes

- ❑ A **base class** is often called the *parent class*
 - A **derived class** is then called a *child class*
- ❑ These relationships are often extended such that a class that is a parent of a parent . . . of another class is called an *ancestor class*
 - If class **A** is an ancestor of class **B**, then class **B** can be called a *descendent* of class **A**

Overriding a Method Definition

- ❑ Although a derived class inherits methods from the base class, it **can change or *override* an inherited method** if necessary
 - In order to override a method definition, a new definition of the method is simply placed in the class definition

Lab

```
import java.util.Date;

public class HourlyEmployee extends Employee{
    private double wageRate;

    public HourlyEmployee(String theName, Date theDate, double rate){
        name = theName;
        hireDate = theDate;
        wageRate = rate;
    }
    public String getName(){
        return "Hourly Employee:" + name;
    }
}
```

Then run Company again!

Changing the Access Permission of an Overridden Method

- ❑ The access permission of an overridden method can be changed **from private** in the base class **to public** (or some other more permissive access) in the derived class
- ❑ However, the access permission of an overridden method **can not be changed from public** in the base class **to a more restricted** access permission in the derived class

Changing the Access Permission of an Overridden Method

- ☐ Given the following method header in a base case:
`private void doSomething()`
- ☐ The following method header is valid in a derived class:
`public void doSomething()`

- ☐ Given the following method header in a base case:
`public void doSomething()`
- ☐ The following method header is not valid in a derived class:
`private void doSomething()`

Pitfall: Overriding Versus Overloading

- ❑ When a method is **overridden**, the new method definition given in the derived class has the **exact same number and types of parameters** as in the base class
- ❑ When a method in a derived class has a **different signature** from the method in the base class, that is **overloading**

The **final** Modifier

- ❑ If the modifier **final** is placed before the definition of a *method*, then that method may not be redefined in a derived class
- ❑ If the modifier **final** is placed before the definition of a *class*, then that class may not be used as a base class to derive other classes

Lab

```
import java.util.Date;

public class Employee {
    protected String name;
    protected Date hireDate;

    public Employee(){}

    public Employee(String theName, Date theDate){
        name = theName;
        hireDate = theDate;
    }

    public Date getHireDate(){
        return hireDate;
    }

    final public String getName(){
        return name;
    }
}
```

Then see what happens in HourlyEmployee!

The super Constructor

- ❑ A derived class uses a constructor from the base class to initialize all the data inherited from the base class

- In order to invoke a constructor from the base class, it uses a special syntax:

```
public derivedClass(int p1, int p2, double p3)
{
    super(p1, p2);
    instanceVariable = p3;
}
```

- In the above example, `super(p1, p2);` is a call to the base class constructor

Lab

Step 1: remove the “final” added in the previous lab.

```
import java.util.Date;

public class HourlyEmployee extends Employee{
    private double wageRate;

    public HourlyEmployee(String theName, Date theDate, double rate){
        super(theName,theDate);
        wageRate = rate;
    }
    public String getName(){
        return "Hourly Employee:" + name;
    }
}
```

Step 2: revise code here

Step 3: then run the Company again!

The **super** Constructor

- ❑ If a derived class constructor does not include an invocation of **super**, then the no-argument constructor of the base class will automatically be invoked
- ❑ Since the inherited instance variables should be initialized, and the base class constructor is designed to do that, then an explicit call to **super** should always be used

Lab

```
class A
{
    int a;
    public A()
    {
        a = 7;
        System.out.println("Step 1");
    }
}
```

```
class B extends A
{
    public B()
    {
        System.out.println("Step 2");
    }

    public static void main(String[] args){
        B bo = new B();
    }
}
```

The `this` Constructor

- ❑ Often, a no-argument constructor uses `this` to invoke an explicit-value constructor
 - No-argument constructor (invokes explicit-value constructor using `this` and default arguments):

```
public ClassName()  
{  
    this(argument1, argument2);  
}
```

- Explicit-value constructor (receives default values):

```
public ClassName(type1 param1, type2 param2)  
{  
    . . .  
}
```

Tip: An Object of a Derived Class Has More than One Type

- ❑ More generally, **an object of a derived class has the type of every one of its ancestor classes**
 - Therefore, **an object of a derived class can be assigned to a variable of any ancestor type**

- ❑ An ancestor type can never be used in place of one of its derived types

Lab

```
import java.util.Date;

public class Company {

    public static void main(String[] args){

        HourlyEmployee hourlyEmployee = new HourlyEmployee("Josephine",
            new Date(114,0,1), 100);

        System.out.println(hourlyEmployee.getName());

        Employee someEmploy = hourlyEmployee;
        printHireDate(someEmploy);
    }

    public static void printHireDate(Employee someEmploy){
        System.out.println(someEmploy.getHireDate());
    }
}
```

Modifiers

Modifier	Class	Package	Subclass	World
public	V	V	V	V
protected	V	V	V	X
default (package access)	V	V	X	X
private	V	X	X	X

Protected and Package Access

- ❑ The **protected** modifier provides very weak protection compared to the **private** modifier
 - It allows direct access for any programmer who defines a suitable derived class
 - Therefore, instance variables should normally not be marked **protected**

Lab

```
import java.util.Date;

public class Employee {

    private String name;
    private Date hireDate;

    public Employee(){}

    public Employee(String theName, Date theDate){
        name = theName;
        hireDate = theDate;
    }

    public Date getHireDate(){
        return hireDate;
    }

    public String getName(){
        return name;
    }

}
```

Lab

```
import java.util.Date;

public class HourlyEmployee extends Employee{
    private double wageRate;

    public HourlyEmployee(String theName, Date theDate, double rate){
        super(theName,theDate);
        wageRate = rate;
    }
    public String getName(){
        return "Hourly Employee:" + super.getName();
    }
}
```

Then run Company again!

Access Modifiers

Display 7.9 Access Modifiers

Tip: "Is a" Versus "Has a"

- ❑ A derived class demonstrates an *"is a"* relationship between it and its base class
 - Forming an "is a" relationship is one way to make a more complex class out of a simpler class
 - For example, an **HourlyEmployee** *"is an"* **Employee**
 - **HourlyEmployee** is a more complex class compared to the more general **Employee** class

Tip: "Is a" Versus "Has a"

- ❑ Another way to make a more complex class out of a simpler class is through a *"has a"* relationship
 - This type of relationship, called *composition*, occurs when a class contains an instance variable of a class type
 - The **Employee** class contains an instance variable, **hireDate**, of the class **Date**, so therefore, an **Employee "has a" Date**

Tip: "Is a" Versus "Has a"

- ❑ Both kinds of relationships are commonly used to create complex classes, often within the same class
 - Since **HourlyEmployee** is a derived class of **Employee**, and contains an instance variable of class **Date**, then **HourlyEmployee** *"is an"* **Employee** and *"has a"* **Date**

You Cannot Use Multiple supers

- ❑ It is only valid to use **super** to invoke a method from a direct parent
 - Repeating **super** will not invoke a method from some other ancestor class
- ❑ For example, if the **Employee** class were derived from the class **Person**, and the **HourlyEmployee** class were derived from the class **Employee**, it would not be possible to invoke the **toString** method of the **Person** class within a method of the **HourlyEmployee** class
super.super.toString() // ILLEGAL!

The Class Object

- ❑ In Java, every class is a descendent of the class **Object**
 - Every class has **Object** as its ancestor
 - Every object of every class is of type **Object**, as well as being of the type of its own class
- ❑ If a class is defined that is not explicitly a derived class of another class, it is still automatically a derived class of the class **Object**

The Class Object

- ❑ The class **Object** is in the package **java.lang** which is always imported automatically
- ❑ Having an **Object** class enables methods to be written with a parameter of type **Object**
 - A parameter of type **Object** can be replaced by an object of any class
 - For example, some library methods accept an argument of type **Object** so they can be used with an argument that is an object of any class

The Class Object

- ❑ The class **Object** has some methods that every Java class inherits
 - For example, the **equals** and **toString** methods
- ❑ Every object inherits these methods from some ancestor class
 - Either the class **Object** itself, or a class that itself inherited these methods (ultimately) from the class **Object**
- ❑ However, these inherited methods should be overridden with definitions more appropriate to a given class
 - Some Java library classes assume that every class has its own version of such methods

Methods of Object

Modifier and Type	Method and Description
protected Object	clone() Creates and returns a copy of this object.
boolean	equals(Object obj) Indicates whether some other object is "equal to" this one.
protected void	finalize() Called by the garbage collector on an object when garbage collection determines that there are no more references to the object.
Class <?>	getClass() Returns the runtime class of this Object.
int	hashCode() Returns a hash code value for the object.
void	notify() Wakes up a single thread that is waiting on this object's monitor.
void	notifyAll() Wakes up all threads that are waiting on this object's monitor.
String	toString() Returns a string representation of the object.
void	wait() Causes the current thread to wait until another thread invokes the notify() method or the notifyAll() method for this object.
void	wait(long timeout) Causes the current thread to wait until either another thread invokes the notify() method or the notifyAll() method for this object, or a specified amount of time has elapsed.
void	wait(long timeout, int nanos) Causes the current thread to wait until another thread invokes the notify() method or the notifyAll() method for this object, or some other thread interrupts the current thread, or a certain amount of real time has elapsed.

The Right Way to Define `equals`

- ❑ Since the `equals` method is always inherited from the class `Object`, methods like the following simply overload it:

```
public boolean equals(Employee otherEmployee)
{ . . . }
```

Lab

```
import java.util.Date;
```

```
public class Employee {  
    private String name;  
    private Date hireDate;
```

```
    public Employee(){}  
  
    public Employee(String theName, Date theDate){  
        name = theName;  
        hireDate = theDate;  
    }  
    public Date getHireDate(){  
        return hireDate;  
    }  
  
    public String getName(){  
        return name;  
    }  
  
    public boolean equals(Employee otherone){  
        if(otherone.getName().equals(this.name) && otherone.getHireDate().equals(this.hireDate)){  
            return true;  
        }else{  
            return false;  
        }  
    }  
}
```

Lab

```
import java.util.Date;

public class CompareTest {

    public static void main(String[] args) {
        Employee employeeA = new Employee("Josephine", new Date(114,0,1));
        Employee employeeB = new Employee("Josephine", new Date(114,0,1));

        System.out.println(employeeA.equals(employeeB));

        System.out.println(employee == employeeB);
    }
}
```

instanceof and getClass

- ❑ Both the **instanceof** operator and the **getClass()** method can be used to check the class of an object
- ❑ However, the **getClass()** method is more exact
 - The **instanceof** operator simply tests the class of an object
 - The **getClass()** method used in a test with **==** or **!=** tests if two objects *were created with* the same class

The `instanceof` Operator

- ❑ The `instanceof` operator checks if an object is of the type given as its second argument

`Object instanceof ClassName`

- This will return `true` if `Object` is of type `ClassName`, and otherwise return `false`
- Note that this means it will return `true` if `Object` is the type of *any descendent class* of `ClassName`

The `getClass()` Method

- ❑ Every object inherits the same `getClass()` method from the `Object` class
 - This method is marked **`final`**, so it cannot be overridden
- ❑ An invocation of `getClass()` on an object returns a representation *only* of the class that was used with **`new`** to create the object
 - The results of any two such invocations can be compared with `==` or `!=` to determine whether or not they represent the exact same class

```
(object1.getClass() == object2.getClass())
```

Lab

```
import java.util.Date;

public class CompareTest {

    public static void main(String[] args) {
        Employee employeeA = new Employee("Josephine", new Date(114,0,1));
        Employee employeeB = new Employee("Josephine", new Date(114,0,1));

        System.out.println(employeeA.equals(employeeB));

        System.out.println(employeeA == employeeB);

        if(employeeA instanceof Employee){
            System.out.println(employeeA.getName() + "is an object of Employee");
        }

        System.out.println(employeeA.getClass().getName());

    }

}
```

Lab

Inheritance is the process by which a new class – known as a _____ - is created from another class, called the _____.

(a) base class, derived class

(b) derived class, base class

(c) inherited class, base class

(d) base class, inherited class

Lab

Inheritance promotes code _____.

(a)reinvention

(b)reuse

(c)repeats

(d)all of the above

Lab

The keyword **extends** indicates:

- (a)encapsulation
- (b)polymorphism
- (c)inheritance
- (d)none of the above

Lab

A derived class is also called a

(a)sub class

(b)super class

(c)base class

(d)all of the above

Lab

A super class is also called a

- (a) derived class
- (b) dominant class
- (c) sub class
- (d) base class

Lab

What does a derived class automatically inherit from the base class?

- (a) instance variables
- (b) static variables
- (c) public methods
- (d) all of the above

Lab

If the final modifier is added to the definition of a method, this means:

- (a) The method may be redefined in the derived class.
- (b) The method may be redefined in the sub class.
- (c) The method may not be redefined in the derived class.
- (d) None of the above.

Lab

The special syntax for invoking a constructor of the base class is:

(a) `super()`

(b) `base()`

(c) `parent()`

(d) `child()`

Lab

If an instance variable is not modified by public, protected or private then it is said to have:

- (a) Package access
- (b) Default access
- (c) Friendly access
- (d) All of the above

Lab

The class _____ is an ancestor class of all Java classes.

(a)String

(b)Object

(c)Math

(d)JFrame

Lab

Consider the classes below, declared in the same file:

```
class A
{
    int a;
    public A()
    {
        a = 7;
    }
}
```

```
class B extends A
{
    int b;
    public B()
    {
        b = 8;
    }
}
```

```
public class ABTest {
    public static void main
        (String[] args){
        B obj1 = new B();

        System.out.println(obj1.a);
        System.out.println(obj1.b);
    }
}
```

Which of the statements below is *false*?

- a. Both variables `a` and `b` are instance variables.
- b. After the constructor for `class B` executes, the variable `a` will have the value 7.
- c. After the constructor for `class B` executes, the variable `b` will have the value 8.
- d. A reference of type `A` can be treated as a reference of type `B`.

- (a) True
- (b) True
- (c) True
- (d) False

Lab

```
public class Bicycle {  
  
    public int speed;  
  
    public Bicycle(int startSpeed) {  
        speed = startSpeed;  
    }  
  
    public void applyBrake(int decrement) {  
        speed -= decrement;  
    }  
  
    public void speedUp(int increment) {  
        speed += increment;  
    }  
  
}
```

Lab

```
public class MountainBike extends Bicycle {  
  
    public int seatHeight;  
  
    public MountainBike(int startHeight,  
                        int startSpeed) {  
        super(startSpeed);  
        seatHeight = startHeight;  
    }  
  
    public void setHeight(int newValue) {  
        seatHeight = newValue;  
    }  
}
```

Lab

```
public class BikeTest {  
  
    public static void main(String[] args) {  
        MountainBike myBike = new MountainBike(10,20);  
  
        for(int i=0;i<100;i++){  
            myBike.speedUp(1);  
        }  
        System.out.println(myBike.speed);  
  
        myBike.setHeight(10);  
        System.out.println(myBike.seatHeight);  
    }  
}
```
