

CHAPTER 8

Polymorphism

(Abstract Class and Interface)

Shin-Jie Lee (李信杰)

Associate Professor

Computer and Network Center

Department of Computer Science and Information Engineering

National Cheng Kung University

Introduction to Polymorphism

- ❑ There are three main programming mechanisms that constitute object-oriented programming (OOP)
 - Encapsulation
 - Inheritance
 - Polymorphism

Introduction to Polymorphism

❑ **Polymorphism:** A same operation can behave differently (be implemented by different methods).

Late Binding

❑ *Early binding or static binding*

- **which method is to be called** is decided at compile-time
 - *Overloading*: an invocation can be operated on arguments of more than one type

❑ *Late binding or dynamic binding*

- **which method is to be called** is decided at runtime
 - *Overriding*: a derived class inherits methods from the base class, it can change or override an inherited method

Lab: Early binding (through overloading)

```
public class SayHello {  
  
    public String sayHello(String name){  
        return "Hello! " + name;  
    }  
  
    public String sayHello(String name, String gender){  
        if(gender.equals("boy")){  
            return "Hello! Mr. " + name;  
        }  
        else if(gender.equals("girl")){  
            return "Hello! Miss. " + name;  
        }else{  
            return "Hello! " + name;  
        }  
    }  
  
    public static void main(String[] args){  
        SayHello hello = new SayHello();  
        System.out.println(hello.sayHello("S.J.")); //decided at compile time  
        System.out.println(hello.sayHello("S.J.", "boy")); //decided at compile time  
    }  
}
```

Lab: Late binding (through overriding)

```
public class Payment {  
    public void pay(){  
        System.out.println("Pay in cash");  
    }  
    public void checkout(){  
        pay();  
    }  
}
```

```
public class Store {  
    public static void main(String[] args) {  
        Payment p1 = new Payment();  
        p1.checkout();  
    }  
}
```

Lab: Late binding (through overriding)

```
public class CreditCardPayment extends Payment{  
    public void pay() {  
        System.out.println("Pay with credit card");  
    }  
}
```

```
public class Store {  
    public static void main(String[] args) {  
        Payment p1 = new Payment();  
        p1.checkout();  
  
        Payment p2 = new CreditCardPayment();  
        p2.checkout();  
    }  
}
```

Pitfall: No Late Binding for Static Methods

- ❑ Java uses **static binding** with **private**, **final**, and **static** methods
 - In the case of **private** and **final** methods, late binding would serve no purpose
 - However, in the case of a static method invoked using a calling object, it does make a difference

Lab

```
public class Payment {  
    public static void pay(){  
        System.out.println("Pay in cash");  
    }  
    public void checkout(){  
        pay();  
    }  
}
```

```
public class CreditCardPayment extends Payment{  
    public static void pay() {  
        System.out.println("Pay with credit card");  
    }  
}
```

Then run Store again!

Lab

```
public class Store {  
    public static void main(String[] args) {  
        Payment p1 = new Payment();  
        p1.checkout();  
  
        Payment p2 = new CreditCardPayment();  
        p2.checkout();  
    }  
}
```

the type of **p2** is determined by its variable name,
not the object that it references

Upcasting and Downcasting

- ❑ *Upcasting* is when an object of a derived class is assigned to a variable of a base class (or any ancestor class)

```
Payment p2 = new CreditCardPayment();  
p2.checkout();
```

Upcasting and Downcasting

- ❑ *Downcasting* is when a type cast is performed from a base class to a derived class (or from any ancestor class to any descendent class)
 - Downcasting has to be done very carefully
 - In many cases it doesn't make sense, or is illegal:

```
Payment p1 = new Payment();  
CreditCardPayment p2 = (CreditCardPayment)p1; //runtime error
```

Tip: Checking to See if Downcasting is Legitimate

- ❑ Downcasting to a specific type is only sensible if the object being cast is an instance of that type
 - This is exactly what the **instanceof** operator tests for:
object instanceof ClassName
 - It will return true if *object* is of type *ClassName*
 - In particular, it will return true if *object* is an instance of any descendent class of *ClassName*

Lab (Downcasting)

Step1: Remove "static" in **CreditCardPayment** and **Payment**

Step2

```
public class CreditCardPayment extends Payment{  
    public void pay() {  
        System.out.println("Pay with credit card");  
    }  
    public void sign(){  
        System.out.println("Signing...");  
    }  
}
```

Lab (Downcasting)

```
public class Store {  
  
    public static void main(String[] args) {  
        Payment p1 = new Payment();  
        p1.checkout();  
        payProcess(p1);  
  
        Payment p2 = new CreditCardPayment();  
        p2.checkout();  
        payProcess(p2);  
    }  
  
    public static void payProcess(Payment p){  
        if(p instanceof CreditCardPayment){  
            ((CreditCardPayment)p).sign();  
        }  
    }  
}
```

A First Look at the `clone` Method

- ❑ Creates and returns a copy of this object.
 - `x.clone() != x`
- ❑ The heading for the `clone` method defined in the `Object` class is as follows:
`protected Object clone()`
- ❑ A change to a more permissive access, such as from `protected` to `public`, is always allowed when overriding a method definition

Lab

```
public class A implements Cloneable{  
    int num = 1;  
    B b = new B();  
  
    public Object clone(){  
        try{  
            return super.clone();  
        }catch(Exception e){  
            return null;  
        }  
    }  
}
```

```
public class B implements Cloneable{  
    int speed = 100;  
}
```

Lab (Shallow Copy)

```
public class Test {  
  
    public static void main(String[] args) {  
        A a = new A();  
        System.out.println(a.num);           //1  
        System.out.println(a.b.speed);       //100  
  
        A clone_a = (A) a.clone();  
        System.out.println(clone_a.num);      //1  
        System.out.println(clone_a.b.speed);  //100  
  
        clone_a.num = 2;  
        clone_a.b.speed = 200;  
        System.out.println(a.num);           //1  
        System.out.println(a.b.speed);       //200  
  
    }  
}
```

A First Look at the `clone` Method

- ❑ If a class has a copy constructor, the `clone` method for that class can use the *copy constructor* to create the copy returned by the `clone` method

```
public Sale clone()  
{  
    return new Sale(this);  
}
```

Lab (Deep Copy)

```
public class A implements Cloneable{
    int num = 1;
    B b = new B();

    public A(A a){
        num = a.num;
        b.speed = a.b.speed;
    }
    public A(){}

    public Object clone(){
        return new A(this);
    }
}
```

Lab (Deep Copy)

```
public class Test {  
  
    public static void main(String[] args) {  
        A a = new A();  
        System.out.println(a.num);           //1  
        System.out.println(a.b.speed);       //100  
  
        A clone_a = (A) a.clone();  
        System.out.println(clone_a.num);      //1  
        System.out.println(clone_a.b.speed);  //100  
  
        clone_a.num = 2;  
        clone_a.b.speed = 200;  
        System.out.println(a.num);           //1  
        System.out.println(a.b.speed);       //100  
  
    }  
}
```

Introduction to Abstract Classes

- ❑ In order to postpone the definition of a method, Java allows an *abstract method* to be declared
 - An abstract method has a heading, but no method body
 - The body of the method is defined in the derived classes
- ❑ The class that contains an abstract method is called an *abstract class*

Abstract Method

- ❑ An abstract method is like a placeholder for a method that will be fully defined in a descendent class
- ❑ It has a complete method heading, to which has been added the modifier **abstract**
- ❑ **It cannot be private**
- ❑ It has no method body, and ends with a semicolon in place of its body

```
public abstract double getPay();  
public abstract void doIt(int count);
```

Abstract Class

- ❑ A class that has at least one abstract method is called an *abstract class*
 - An abstract class must have the modifier **abstract** included in its class heading:

```
public abstract class Employee
{
    private instanceVariables;
    . . .
    public abstract double getPay();
    . . .
}
```

Abstract Class

- An abstract class can have any number of abstract and/or fully defined methods
- If a derived class of an abstract class adds to or does not define all of the abstract methods, then it is abstract also, and must add **abstract** to its modifier
- ❑ A class that has no abstract methods is called a *concrete class*

Pitfall: You Cannot Create Instances of an Abstract Class

- ❑ An abstract class can only be used to derive more specialized classes
 - While it may be useful to discuss employees in general, in reality an employee must be a salaried worker or an hourly worker
- ❑ **An abstract class can have constructors, but they cannot be used to create an object of the abstract class**

Lab

```
public abstract class Animal {  
    public Animal(){ System.out.println("I am animal");}  
    public abstract void run();  
    public void sit(){ System.out.println("Sit down..."); }  
    public static void sleep(){System.out.println("Sleep");}  
}
```

```
public class Dog extends Animal {  
    public void run(){  
        System.out.println("The dog is running");  
    }  
}
```

```
public class Cat extends Animal{  
    public void run(){  
        System.out.println("The cat is running");  
    }  
}
```

Lab

```
public class House {  
  
    public static void main(String[] args) {  
        Animal dog = new Dog();  
        Animal cat = new Cat();  
  
        playWith(dog);  
        playWith(cat);  
  
        dog.sit();  
        cat.sit();  
    }  
  
    public static void playWith(Animal animal){  
        animal.run();  
    }  
}
```

Interfaces

- ❑ An *interface* is something like an extreme case of an abstract class
 - However, *an interface is not a class*
 - *It is a type that can be satisfied by any class that implements the interface*
- ❑ The syntax for defining an interface is similar to that of defining a class
 - Except the word **interface** is used in place of **class**

Interfaces

- ❑ An interface specifies a set of methods that any class that implements the interface must have
 - It contains **method headings** and **constant definitions** only
 - Any variables defined in an interface must be public, static, and final
 - It contains **no instance variables**
 - It can contain **concrete and static methods** after **Java 8**

```
default void say(){  
    System.out.println("Hello, this is default method");  
}  
  
static void sayLouder(String msg){  
    System.out.println(msg);  
}
```

Lab (Constants)

```
public interface Shape {  
    int color = 1; // => public static final int color = 1;  
}
```

```
public class Paint {  
    public static void main(String[] args) {  
        System.out.println(Shape.color);  
    }  
}
```

Interfaces

- ❑ All methods in an interface are **implicitly public and abstract**, so you can omit the public modifier.
 - They cannot be given private or protected

```
public interface ISpec1 {  
    //Not allowed  
    private void run();  
    protected void run();  
  
    //Allowed  
    void run();  
    public abstract void run();  
    default void run(){ ... }  
    static void run(){ ... }  
}
```

Interfaces

- ❑ *Multiple inheritance* is not allowed in Java
- ❑ Instead, Java's way of approximating multiple inheritance is through interfaces

```
public class ConcreteClass implements ISpec1, ISpec2, ISpec3{  
    ...  
}
```

Interfaces

- ❑ To *implement an interface*, a concrete class must do two things:

1. `implements Interface_Name`

2. The class must implement *all* the method headings listed in the definition(s) of the interface(s)

Lab

```
public interface Shape {  
    int color = 1;  
    default void echo(){ System.out.println("Shape"); log();}  
    private void log(){ System.out.println("Log");}  
    static void erase(){ System.out.println("Erase");}  
    double area();  
}
```

```
public class Circle implements Shape {  
  
    double radius = 3;  
  
    public double area() {  
        return radius * radius * 3.14;  
    }  
  
    public static void main(String args[]) {  
        Circle c = new Circle();  
        c.echo();  
        c.area();  
        Shape.erase();  
    }  
}
```

Lab

```
public class Paint {  
  
    public static void main(String[] args) {  
        System.out.println(Shape.color);  
  
        Shape shape1 = new Rectangle();  
        printArea(shape1);  
  
        Shape shape2 = new Circle();  
        printArea(shape2);  
    }  
  
    public static void printArea(Shape shape){  
        System.out.println(shape.area());  
    }  
}
```

Abstract Classes Implementing Interfaces

- ❑ Abstract classes may implement one or more interfaces
 - Any method headings given in the interface that are not given definitions are made into abstract methods
- ❑ A concrete class must give definitions for all the method headings given in the abstract class *and the interface*

Abstract Class vs. Interface

```
public abstract class Shape {  
    int color = 1; // not final  
    public Shape() { System.out.println("Constructor"); }  
    public void echo() { System.out.println("Shape"); log(); }  
    private void log() { System.out.println("Log"); }  
    public static void erase() { System.out.println("Erase"); }  
    public abstract double area();  
}
```

VS.

```
public interface Shape {  
    int color = 1; // final  
    default void echo() { System.out.println("Shape"); log(); }  
    private void log() { System.out.println("Log"); }  
    static void erase() { System.out.println("Erase"); }  
    double area();  
}
```

Derived Interfaces

- ❑ Like classes, an interface may be derived from a base interface
 - This is called *extending* the interface
 - The derived interface must include the phrase
extends BaseInterfaceName
- ❑ A concrete class that implements a derived interface must have definitions for any methods in the derived interface as well as any methods in the base interface

Lab

```
public interface Drawing {  
    public abstract void drawBorder();  
}
```

```
public interface Shape extends Drawing{  
    int color = 1; // => public static final int color = 1;  
    public abstract double area();  
}
```

Lab

```
public class Rectangle implements Shape{

    int x1=0;
    int y1=0;
    int x2=10;
    int y2=10;

    public double area(){
        return (x2-x1)*(y2-y1);
    }
    public void drawBorder(){
        System.out.println("Drawing the border of the rectangle...");
    }
}
```

Lab

```
public class Circle implements Shape{
```

```
    double radius = 3;  
    public double area(){  
        return radius*radius*3.14;  
    }
```

```
    public void drawBorder(){  
        System.out.println("Drawing the border of the circle...");  
    }  
}
```

Lab

```
public interface Printable {  
    void printAll();  
}
```

```
class Person implements Printable {  
    private String name = new String("Bill");  
    private int age = 22;  
  
    public void printAll() {  
        System.out.println("Name is " + name + ", age is " + age);  
    }  
}
```

```
public class PrintableTest {  
    public static void main(String[] args) {  
        Printable p = new Person();  
        p.printAll();  
    }  
}
```

Anonymous Class

Anonymous classes enable **you to make your code more concise**.
They enable you to declare and instantiate a class at the same time.

```
interface Person {  
    abstract void eat(String food);  
    abstract void run();  
}  
  
class Demo {  
    public static void main(String args[]) {  
        Person p = new Person() { //Anonymous Class  
            public void eat(String food) {  
                System.out.println(food);  
            }  
            public void run() {  
                System.out.println("running");  
            }  
        };  
        p.eat("pizza");  
    }  
}
```

Functional Interface

A **functional interface** is an interface that contains only one abstract method

```
interface Person {  
    abstract void eat(String food);  
    abstract void run();  
}
```

Lambda Expression

(簡化版Anonymous Class)

- Lambda expressions basically express instances of functional interfaces
 - (p1, p2) -> System.out.println("Multiple parameters: " + p1 + ", " + p2);

```
class Demo {  
    public static void main(String args[]) {  
        Person p = (food)->{  
            System.out.println(food);  
        };  
        p.eat("Pizza");  
    }  
}
```

or

```
class Demo {  
    public static void main(String args[]) {  
        Person p = food->System.out.println(food);  
        p.eat("Pizza");  
    }  
}
```

Predefined Functional Interfaces

Interface Consumer<T>

void

accept(T t)

Performs this operation on the given argument.

Interface Supplier<T>

T

get()

Gets a result.

Interface Function<T,R>

R

apply(T t)

Applies this function to the given argument.

Interface Predicate<T>

boolean

test(T t)

Evaluates this predicate on the given argument.

Lab (Consumer)

```
import java.util.Arrays;
import java.util.List;
import java.util.function.Consumer;

class Demo {
    public static void main(String args[]) {

        List<String> cities = Arrays.asList("Dhaka", "New York", "London");

        Consumer<List<String>> upperCaseConsumer = list -> {
            for (int i = 0; i < list.size(); i++) {
                list.set(i, list.get(i).toUpperCase());
                System.out.println(list.get(i));
            }
        };

        upperCaseConsumer.accept(cities);
    }
}
```

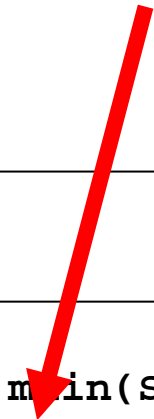

Method Reference

(再簡化版Anonymous Class)

- A method reference is the shorthand syntax for a lambda expression that contains just one method call

```
class Demo {  
    public static void main(String args[]) {  
        Person p = food->System.out.println(food);  
        p.eat("Pizza");  
    }  
}
```

```
class Demo {  
    public static void main(String args[]) {  
        Person p = System.out::println;  
        p.eat("Pizza");  
    }  
}
```

Using Lambda Expression as an Argument

```
import java.util.ArrayList;

class Demo {
    public static void main(String args[]) {
        ArrayList<Integer> arrL = new ArrayList<Integer>();
        arrL.add(1);
        arrL.add(2);
        arrL.add(3);

        arrL.forEach( (anything) -> System.out.println(anything));
    }
}
```

Class ArrayList<E>

void

forEach(Consumer<? super E> action)

Performs the given action for each element of the Iterable until all elements have been processed or the action throws an exception.

Interface Consumer<T> This is a functional interface

void

accept(T t)

Performs this operation on the given argument.

Lab

```
import java.util.*;
import java.util.function.Consumer;

public class Demo {
    public static void main(String[] args) {

        List<String> strList = Arrays.asList("A", "B", "C");

        // Anonymous class (匿名類別)
        strList.forEach(new Consumer<String>() {
            @Override
            public void accept(String s) {
                System.out.print(s); // ABC
            }
        });

        // Lambda expression
        strList.forEach(s -> System.out.print(s)); // ABC

        // Method reference (方法參考)
        strList.forEach(System.out::print); // ABC

        // Method reference (方法參考) 使用靜態方法
        strList.forEach(Demo::static_printList); // ABC

        // Method reference (方法參考) 使用實例方法
        Demo demo = new Demo();
        strList.forEach(demo::instance_printList); // ABC
    }
    private static void static_printList(String s) {
        System.out.print(s);
    }
    private void instance_printList(String s) {
        System.out.print(s);
    }
}
```
