

# CHAPTER3 Console Input and Output

Shin-Jie Lee (李信杰)
Associate Professor
Computer and Network Center
Department of Computer Science and Information Engineering
National Cheng Kung University

# System.out.println for console output

- System.out is an object that is part of the Java language
- □ println is a method invoked by the System.out object that can be used for console output
  - The data to be output is given as an argument in parentheses
  - > A plus sign is used to connect more than one item
  - > Every invocation of **println** ends a line of output System.out.println("The answer is " + 42);

## println Versus print

- Another method that can be invoked by the **System.out** object is **print**
- ☐ The print method is like println, except that it does not end a line
  - With println, the next output goes on a new line
  - > With print, the next output goes on the same line

# Formatting Output with printf

- ☐ Starting with version 5.0, Java includes a method named printf that can be used to produce output in a specific format
- ☐ The Java method **printf** is similar to the **print** method
  - Like **print**, **printf** does not advance the output to the next line
- □ **System.out.printf** can have any number of arguments
  - ➤ The first argument is always a *format string* that contains one or more *format specifiers* for the remaining arguments
  - ➤ All the arguments except the first are values to be output to the screen

## printf Format Specifier

```
The code
       double price = 19.8;
       System.out.print("$");
       System.out.printf("%6.2f", price);
       System.out.println(" each");
  will output the line
       $ 19.80 each
☐ The format string "%6.2f" indicates the following:
    End any text to be output and start the format specifier (%)
    > Display up to 6 right-justified characters, pad fewer than six characters on
       the left with blank spaces (i.e., field width is 6)
    > Display exactly 2 digits after the decimal point (.2)
    > Display a floating point number, and end the format specifier (i.e., the
       conversion character is f)
```

### Right and Left Justification in printf

# Multiple arguments with printf

- ☐ The following code contains a **printf** statement having three arguments

\$ 19.80 for each magic apple.

Wow

- ➤ Note that the first argument is a format string containing two format specifiers (%6.2f and %s)
- These format specifiers match up with the two arguments that follow (price and name)

## Line Breaks with printf

```
☐ Line breaks can be included in a format string
  using %n
☐ The code
      double price = 19.8;
      String name = "magic apple";
      System.out.printf("$%6.2f for each %s.%n",
        price, name);
      System.out.println("Wow");
  will output
      $ 19.80 for each magic apple.
      Wow
```

### Display 2.1 Format Specifiers for System.out.printf

CONVERSION CHARACTER	TYPE OF OUTPUT	EXAMPLES
d	Decimal (ordinary) integer	%5d %d
f	Fixed-point (everyday notation) floating point	%6.2f %f
е	E-notation floating point	%8.3e %e
g	General floating point (Java decides whether to use E-notation or not)	%8.3g %g
S	String	%12s %s
С	Character	%2c %c

### Display 2.2 The printf Method

```
public class PrintfDemo
 2
        public static void main(String[] args)
 3
            String aString = "abc";
 5
            System.out.println("String output:");
 6
            System.out.println("START1234567890");
8
             System.out.printf("START%sEND %n", aString);
9
             System.out.printf("START%4sEND %n", aString);
            System.out.printf("START%2sEND %n", aString);
10
            System.out.println();
11
                                                                         (continued)
```

### Display 2.2 The printf Method

```
12
            char oneChracter = 'Z';
            System.out.println("Character output:");
13
            System.out.println("START1234567890");
14
15
            System.out.printf("START%cEND %n", oneCharacter);
16
            System.out.printf("START%4cEND %n", oneCharacter);
            System.out.println();
17
18
            double d = 12345.123456789;
19
            System.out.println("Floating-point output:");
20
            System.out.println("START1234567890");
            System.out.printf("START%fEND %n", d);
                                                       //12345.123457
21
            System.out.printf("START%.4fEND %n", d);
                                                     //12345.1235
22
23
            System.out.printf("START%.2fEND %n", d);
                                                     //12345.12
            System.out.printf("START%12.4fEND %n", d); // 12345.1235
24
            System.out.printf("START%eEND %n", d); //1.234512e+04
25
26
            System.out.printf("START%12.5eEND %n", d); // 1.23451e+04
27
        }
28
    }
```

(continued)

### Formatting Money Amounts with printf

- ☐ A good format specifier for outputting an amount of money stored as a double type is %.2f
- ☐ It says to include exactly two digits after the decimal point and to use the smallest field width that the value will fit into:

```
double price = 19.99;
System.out.printf("The price is $%.2f each.")
produces the output:
   The price is $19.99 each.
```

## **Money Formats**

- ☐ Using the NumberFormat class enables a program to output amounts of money using the appropriate format
  - > The NumberFormat class must first be imported in order to use it

### import java.text.NumberFormat

- An object of **NumberFormat** must then be created using the **getCurrencyInstance()** method
- The **format** method takes a floating-point number as an argument and returns a **String** value representation of the number in the local currency

## **Importing Packages and Classes**

- ☐ Libraries in Java are called *packages* 
  - ➤ A package is a collection of classes that is stored in a manner that makes it easily accessible to any program
  - In order to use a class that belongs to a package, the class must be brought into a program using an *import* statement
  - Classes found in the package java.lang are imported automatically into every Java program

```
import java.text.NumberFormat;
// import theNumberFormat class only
import java.text.*;
//import all the classes in package java.text
```

## **Money Formats**

```
import java.text.NumberFormat;
public class CurrencyFormatDemo
  public static void main(String[] args)
                                                得到符號$
    System.out.println("Default location:"); 如果()加上Locale.地點,即可顯示不
                                                同的幣別 e.g. Locale.TAIWAN (NT)
    NumberFormat moneyFormater =
                     NumberFormat.getCurrencyInstance();
    System.out.println(moneyFormater.format(19.8));
    System.out.println(moneyFormater.format(19.81111));
    System.out.println(moneyFormater.format(19.89999));
    System.out.println(moneyFormater.format(19));
    System.out.println();
```

# Money Formats

☐ Output of the previous program

```
Default location:
$19.80
$19.81
$19.90
$19.00
```

## **Specifying Locale**

- ☐ Invoking the **getCurrencyInstance()**method without any arguments produces an object that will format numbers according to the default location
- In contrast, the location can be explicitly specified by providing a location from the **Locale** class as an argument to the **getCurrencyInstance()** method
  - ➤ When doing so, the **Locale** class must first be imported

```
import java.util.Locale;
```

## **Specifiying Locale**

```
import java.text.NumberFormat;
import java.util.Locale;
public class CurrencyFormatDemo
  public static void main(String[] args)
    System.out.println("US as location:");
    NumberFormat moneyFormater2 =
      NumberFormat.getCurrencyInstance(Locale.US);
    System.out.println(moneyFormater2.format(19.8));
    System.out.println(moneyFormater2.format(19.81111));
    System.out.println(moneyFormater2.format(19.89999));
    System.out.println(moneyFormater2.format(19));
```

## **Specifying Locale**

☐ Output of the previous program

```
US as location:
$19.80
$19.81
$19.90
$19.00
```

# **Locale Constants for Currencies of Different Countries**

### Display 2.4 Locale Constants for Currencies of Different Countries

Locale. CANADA Canada (for currency, the format is the same as US)

Locale.CHINA China

Locale.FRANCE France

Locale.GERMANY Germany

Locale.ITALY Italy

Locale.JAPAN Japan

Locale.KOREA Korea

Locale.TAIWAN Taiwan

Locale.UK United Kingdom (English pound)

Locale.US United States

# Lab

```
import java.text.NumberFormat;
import java.util.Locale;
public class CurrencyFormatDemo
  public static void main(String[] args)
    System.out.println("Taiwan as location:");
    NumberFormat moneyFormater2 =
      NumberFormat.getCurrencyInstance(Locale.TAIWAN);
    System.out.println(moneyFormater2.format(19.8));
    System.out.println(moneyFormater2.format(19.81111));
    System.out.println(moneyFormater2.format(19.89999));
    System.out.println(moneyFormater2.format(19));
```

# Output

```
Taiwan as location:
```

NT\$19.80

NT\$19.81

NT\$19.90

NT\$19.00

### The DecimalFormat Class

- ☐ Using the DecimalFormat class enables a program to format numbers in a variety of ways
  - > The DecimalFormat class must first be imported
  - ➤ A **DecimalFormat** object is associated with a pattern when it is created using the new command
  - ➤ The object can then be used with the method **format** to create strings that satisfy the format
  - An object of the class **DecimalFormat** has a number of different methods that can be used to produce numeral strings in various formats

# The DecimalFormat Class (Part 1 of 3)

### Display 2.5 The DecimalFormat Class

```
import java.text.DecimalFormat;
1
    public class DecimalFormatDemo
                                                                  字,前後沒有則都要補零
        public static void main(String[] args)
            DecimalFormat pattern00dot000 = new DecimalFormat("00.000");
 6
            DecimalFormat pattern0dot00 = new DecimalFormat("0.00");
            double d = 12.3456789;
 8
 9
            System.out.println("Pattern 00.000");
            System.out.println(pattern00dot000.format(d));
10
            System.out.println("Pattern 0.00");
11
12
            System.out.println(pattern0dot00.format(d));
            double money = 19.8;
13
            System.out.println("Pattern 0.00");
14
            System.out.println("$" + pattern0dot00.format(money));
15
16
17
            DecimalFormat percent = new DecimalFormat("0.00%");

### Display 2.5 The DecimalFormat Class

```
public class DecimalFormatDemo {
 public static void main(String[] args) {
  DecimalFormat df = new DecimalFormat("00.000");
  String str = df.format(1.23);
  System.out.println(str);
  DecimalFormat df2 = new DecimalFormat("#0.###");
  String str2 = df2.format(1.23);
  System.out.println(str2);
 Output:
 01,230
 1.23
```

- ☐ Starting with version 5.0, Java includes a class for doing simple keyboard input named the **Scanner** class
- ☐ In order to use the **Scanner** class, a program must include the following line near the start of the file:
  - import java.util.Scanner
- ☐ This statement tells Java to
  - ➤ Make the **Scanner** class available to the program
  - Find the **Scanner** class in a library of classes (i.e., Java *package*) named **java.util**

- ☐ The following line creates an object of the class

  Scanner and names the object keyboard:

  Scanner keyboard = new Scanner(System.in);
- Once a **Scanner** object has been created, a program can then use that object to perform keyboard input using methods of the **Scanner** class

□ The method nextInt reads one int value typed in at the keyboard and assigns it to a variable:
 int numberOfPods = keyboard.nextInt();
 □ The method nextDouble reads one double value typed in at the keyboard and assigns it to a variable:
 double d1 = keyboard.nextDouble();
 □ Multiple inputs must be separated by whitespace and read by multiple invocations of the appropriate method

 ▶ Whitespace is any string of characters, such as blank spaces, tabs, and line breaks that print out as white space

- ☐ The method next reads one string of non-whitespace characters delimited by whitespace characters such as blanks or the beginning or end of a line
- ☐ Given the code

```
String word1 = keyboard.next();
String word2 = keyboard.next();
and the input line
jelly beans
```

The value of word1 would be jelly, and the value of word2 would be beans

The method **nextLine** reads an entire line of keyboard input ☐ The code, String line = keyboard.nextLine(); reads in an entire line and places the string that is read into the variable line The end of an input line is indicated by the escape sequence '\n' This is the character input when the **Enter** key is pressed > On the screen it is indicated by the ending of one line and the beginning of the next line ☐ When **nextLine** reads a line of text, it reads the '\n' character, so the next reading of input begins on the next line ➤ However, the '\n' does not become part of the string value returned (e.g., the string named by the variable line above does not end with the '\n' character)

# **Keyboard Input Demonstration** (Part 1 of 2)

### Display 2.6 Keyboard Input Demonstration

```
import java.util.Scanner;
                                                  Makes the Scanner class available to
                                                  your program.
    public class ScannerDemo
                                                          Creates an object of the class
       public static void main(String[] args)
                                                           Scanner and names the
                                                          object keyboard.
          Scanner keyboard = new Scanner(System.in);
          System.out.println("Enter the number of pods followed by");
          System.out.println("the number of peas in a pod:");
          int numberOfPods = keyboard.nextInt();
Each reads one int
          int peasPerPod = keyboard.nextInt();
10
                                                               from the keyboard
11
          int totalNumberOfPeas = numberOfPods*peasPerPod;
          System.out.print(numberOfPods + " pods and ");
12
13
          System.out.println(peasPerPod + " peas per pod.");
          System.out.println("The total number of peas = "
14
                                               + totalNumberOfPeas);
15
16
17
```

(continued)

# **Keyboard Input Demonstration** (Part 2 of 2)

### Display 2.6 Keyboard Input Demonstration

#### SAMPLE DIALOGUE 1

Enter the number of pods followed by the number of peas in a pod:

22 10

22 pods and 10 peas per pod.

The total number of peas = 220

The numbers that are input must be separated by whitespace, such as one or more blanks.

#### SAMPLE DIALOGUE 2

Enter the number of pods followed by the number of peas in a pod:

22

10

22 pods and 10 peas per pod.

The total number of peas = 220

A line break is also considered whitespace and can be used to separate the numbers typed in at the keyboard.

### Display 2.7 Another Keyboard Input Demonstration

SAMPLE DIALOGUE

#### Display 2.7 Another Keyboard Input Demonstration

# Enter two whole numbers separated by one or more spaces: 42 43 You entered 42 and 43 Next enter two numbers. A decimal point is OK. 9.99 57 You entered 9.99 and 57.0 Next enter two words: jelly beans You entered "jelly" and "beans" Next enter a line of text: Java flavored jelly beans are my favorite.

You entered "Java flavored jelly beans are my favorite."

# Pitfall: Dealing with the Line Terminator, '\n'

The method **nextLine** of the class **Scanner** reads the remainder of a line of text starting wherever the last keyboard reading left off This can cause problems when combining it with different methods for reading from the keyboard such as **nextInt** ☐ Given the code, Scanner keyboard = new Scanner(System.in); int n = keyboard.nextInt(); String s1 = keyboard.nextLine(); String s2 = keyboard.nextLine(); and the input, 2 Heads are better than 1 head. what are the values of **n**, **s1**, and **s2**?

# Pitfall: Dealing with the Line Terminator, '\n'

```
☐ Given the code and input on the previous slide
   n will be equal to "2",
   s1 will be equal to "", and
   s2 will be equal to "heads are better than"
☐ If the following results were desired instead
   n equal to "2",
   s1 equal to "heads are better than", and
   s2 equal to "1 head"
  then an extra invocation of nextLine would be needed
  to get rid of the end of line character ('\n')
```

```
public class ScannerDemo {
 public static void main(String[] args) {
    Scanner scanner = new Scanner(System.in);
    int num = scanner.nextInt();
    System.out.println("num="+num);
    scanner.nextLine();
    String line2 = scanner.nextLine();
    System.out.println("line="+line2);
  Console:
  12
  num=12
  Hello World
  line=Hello World
```

```
public class ScannerDemo {
  public static void main(String[] args) {
    Scanner scanner = new Scanner(System.in);
    String line1 = scanner.nextLine();
    int num = Integer.valueOf(line1);
    System.out.println("num="+num);
    String line2 = scanner.nextLine();
    System.out.println("line:"+line2);
    Console:
    12
    num=12
    Hello World
    line=Hello World
```

## Methods in the Class Scanner (Part 1 of 3)

#### Display 2.8 Methods of the Scanner Class

The Scanner class can be used to obtain input from files as well as from the keyboard. However, here we are assuming it is being used only for input from the keyboard.

To set things up for keyboard input, you need the following at the beginning of the file with the keyboard input code:

```
import java.util.Scanner;
```

You also need the following before the first keyboard input statement:

Scanner Scannner\_Object\_Name = new Scanner(System.in);

The Scannner\_Object\_Name can then be used with the following methods to read and return various types of data typed on the keyboard.

Values to be read should be separated by whitespace characters, such as blanks and/or new lines. When reading values, these whitespace characters are skipped. (It is possible to change the separators from whitespace to something else, but whitespace is the default and is what we will use.)

Scannner\_Object\_Name.nextInt()

Returns the next value of type int that is typed on the keyboard.

(continued)

## Methods in the Class Scanner (Part 2 of 3)

#### Display 2.8 Methods of the Scanner Class

Returns the next value of type float that is typed on the keyboard.

Scannner\_Object\_Name.nextLong()

Returns the next value of type long that is typed on the keyboard.

Scannner\_Object\_Name.nextByte()

Returns the next value of type byte that is typed on the keyboard.

Scannner\_Object\_Name.nextShort()

Returns the next value of type short that is typed on the keyboard.

Scannner\_Object\_Name.nextDouble()

Returns the next value of type double that is typed on the keyboard.

Scannner\_Object\_Name.nextFloat()

(continued)

# Methods in the Class Scanner (Part 3 of 3)

#### Display 2.8 Methods of the Scanner Class

Scannner\_Object\_Name.next()

Returns the String value consisting of the next keyboard characters up to, but not including, the first delimiter character. The default delimiters are whitespace characters.

Scannner\_Object\_Name.nextBoolean()

Returns the next value of type boolean that is typed on the keyboard. The values of true and false are entered as the strings "true" and "false". Any combination of upper- and/or lowercase letters is allowed in spelling "true" and "false".

Scanner\_Object\_Name.nextLine()

Reads the rest of the current keyboard input line and returns the characters read as a value of type String. Note that the line terminator '\n' is read and discarded; it is not included in the string returned.

Scanner\_Object\_Name.useDelimiter(New\_Delimiter);

Changes the delimiter for keyboard input with *Scanner\_Object\_Name*. The *New\_Delimiter* is a value of type String. After this statement is executed, *New\_Delimiter* is the only delimiter that separates words or numbers. See the subsection "Other Input Delimiters" for details.

# **Programming Tip: Prompt for Input**

☐ A program should always prompt the user when he or she needs to input some data:

```
System.out.println(
   "Enter the number of pods followed by");
System.out.println(
   "the number of peas in a pod:");
```

### **Programming Tip: Echo Input**

- ☐ Always echo all input that a program receives from the keyboard
- ☐ In this way a user can check that he or she has entered the input correctly
  - ➤ Even though the input is automatically displayed as the user enters it, echoing the input may expose subtle errors (such as entering the letter "O" instead of a zero)

### The Empty String

- ☐ A string can have any number of characters, including zero characters
  - > "" is the empty string
- ☐ When a program executes the **nextLine** method to read a line of text, and the user types nothing on the line but presses the **Enter** key, then the **nextLine** Method reads the empty string

### **Other Input Delimiters**

- ☐ The delimiters that separate keyboard input can be changed when using the Scanner class
   ☐ For example, the following code could be used to create a Scanner object and change the delimiter from whitespace to "##"
  - Scanner keyboard2 = new Scanner(System.in);
    Keyboard2.useDelimiter("##");
- ☐ After invocation of the useDelimiter method, "##" and not whitespace will be the only input delimiter for the input object keyboard2

# Changing the Input Delimiter (Part 1 of 3)

#### Display 2.10 Changing the Input Delimiter

```
1 import java.util.Scanner;

2 public class DelimiterDemo

3 {
4    public static void main(String[] args)
5    {
6        Scanner keyboard1 = new Scanner(System.in);
7        Scanner keyboard2 = new Scanner(System.in);
8        keyboard2.useDelimiter("##"); 輸入的時候就直接刪除不必要的字串 e.g. ##

9        //Delimiter for keyboard1 is whitespace.
10        //Delimiter for keyboard2 is ##.
```

(continued)

# Changing the Input Delimiter (Part 2 of 3)

#### Changing the Input Delimiter Display 2.10 String word1, word2; 11 12 System.out.println("Enter a line of text:"); word1 = keyboard1.next(); 13 14 word2 = keyboard1.next(); 15 System.out.println("For keyboard1 the two words read are:"); 16 System.out.println(word1); System.out.println(word2); 17 String junk = keyboard1.nextLine(); //To get rid of rest of line. 18 19 20 System.out.println("Reenter the same line of text:"); 21 word1 = keyboard2.next(); 22 word2 = keyboard2.next(); 23 System.out.println("For keyboard2 the two words read are:"); System.out.println(word1); 24 25 System.out.println(word2); 26 27 }

(continued)

#### Display 2.10 Changing the Input Delimiter

### Enter a line of text: one two##three##

For keyboard1 the two words read are:

one

two##three##

SAMPLE DIALOGUE

Reenter the same line of text:

one two##three##

For keyboard2 the two words read are:

one two

three

# Lab

```
public class ScannerDemo {
  public static void main(String[] args) {
    Scanner scanner = new Scanner(System.in);
    scanner.useDelimiter("##");
    int a = scanner.nextInt();
    int b = scanner.nextInt();
    System.out.println(a);
    System.out.println(b);
  }
Input:
12##13##
Output:
12
13
```

# Introduction to File Input/Output

- ☐ The Scanner class can also be used to read from files on the disk
- ☐ Here we only present the basic structure of reading from text files
  - ➤ By covering the basics here your programs can work with real-world data that would otherwise be too much work to type into your program every time it is run

- ☐ Import the necessary classes in addition to scanner
  - import java.io.FileInputStream;
    import java.io.FileNotFoundException;
- Open the file inside a try/catch block
  - ➤ If an error occurs while trying to open the file then execution jumps to the catch block
- ☐ Use nextInt(), nextLine(), etc. to read from the Scanner like reading from the console, except the input comes from the file

### Try/Catch Block

```
Scanner fileIn = null ; // initializes fileIn to empty
try
       // Attempt to open the file
       fileIn = new Scanner( new FileInputStream("PathToFile"));
catch (FileNotFoundException e)
       // If the file could not be found, this code is executed
       // and then the program exits
       System.out.println("File not found.");
       System.exit(0);
catch (IOException e)
   Code continues here
```

Display 2.11 Sample Text File, player.txt, to Store a Player's High Score and Name

41
```

#### Sample Dialogue

```
Text left to read? true

Name: Gordon Freeman

High score: 100510

Text left to read? False
```

```
import java.io.FileInputStream;
import java.util.Scanner;
public class FileTest {
           public static void main(String[] args) {
                      try{
                                  Scanner scanner = new Scanner(new FileInputStream("d:\\test.txt"));
                                  String name = scanner.nextLine();
                                  String id = scanner.nextLine();
                                  String school = scanner.nextLine();
                                  System.out.println("Name:"+name);
                                  System.out.println("ID:"+id);
                                  System.out.println("School:"+school);
                      }catch(Exception e){
                                  e.printStackTrace();
                      }
```

Which statement or group of statements produces the output:

### Java programming is fun!

```
(a) System.out.print(Java programming);
    System.out.print(is fun!);

(b) System.out.println(Java programming is fun!);

(c) System.out.println("Java programming");
    System.out.println(" is fun!");

(d) System.out.print("Java programming")
    System.out.print("Java programming");
    System.out.println(" is fun!");
```

The statement: System.out.printf("%6.2f", 597.7231); displays:

- (a) 597.723
- (b) 597.72
- (c) 000597.72
- (d) None of the above

#### Standard code libraries in Java are called:

- (a) Methods
- (b) Classes
- (c) Packages
- (d) Statements

### What does the following code output?

```
DecimalFormat percent = new DecimalFormat("0.00%");
System.out.println(percent.format(0.308));
```

- (a) 3.080%
- (b) 30.80%
- (c) .0308%
- (d) 308.0%

```
import java.util.Scanner;
public class ConsoleMultiply
             public static void main(String[] args)
                          //Create the scanner object for console input
                          Scanner keyboard = new Scanner(System.in);
                          //Prompt the user for the first number
                          System.out.print("Enter the first integer: ");
                          //Read the input
                          int firstNumber = keyboard.nextInt();
                          //Prompt the user for the second number
                          System.out.print("Enter the second integer: ");
                          //Read the second number
                          int secondNumber = keyboard.nextInt();
                          System.out.println(firstNumber + "*" + secondNumber + " is "
                                       + firstNumber * secondNumber);
             }
```

```
public class ScannerDemo {
  public static void main(String[] args) {
    try{
        Scanner scanner = new Scanner(new FileInputStream("d:\\test.txt"));
        while(scanner.hasNextLine()){
            String line = scanner.nextLine();
            System.out.println(line);
    }catch(Exception e){
       e.printStackTrace();
